ABSTRACT

An apparatus for capacitively determining a position of a counter wheel (1) in a wheel counter mechanism has fixed electrodes (3, 3') at a distance the counter wheel (1). Extending over the circumference of the counter wheel (1) are a sequence measurement electrodes (12,12', 12''), electrically nonconductive sections (13, 13') arranged between said measurement electrodes. This means that it possible to detect either a high orа low capacitance value, that is to say a binary value of either 0 or 1, for each position of the counter wheel and for each fixed electrode. According to the number fixed electrodes for each counter wheel, binary values can be combined to form a representation of any desired number characterizing the current position of the counter wheel (1).
